Lab 4. Variables and Workspaces

Contents

Overview

This lab will modify existing code that has been used successfully to deploy a 'hard-coded' basic VPC architecture.

Start Lab

1. Ensure you have completed Lab0 before attempting this lab.
2. In the IDE terminal pane, enter the following commands…

   ```
   cd ~/environment/awslabs/04
   ```

3. This shifts your current working directory to awslabs/labs/04. Ensure all commands are executed in this directory
4. Close any open files and use the Explorer pane to navigate to and open the pre-configured main.tf file in awslabs/04.

Solution

There is no solution code for this lab as it involves multiple deployment phases. Reach out to your instructor if you encounter issues.

Task 1- Review provisioned terraform files

1. Review the provisioned files in awslabs\04..

   main.tf Hard coded deployment of an EC2 instances in "**us-west-2**". This represents the resources we are to create, in production there would be many other resources defined here. There is also an output block (lines 15-23) which displays information about the deployment, including the workspace.

   variables.tf All content currently commented out

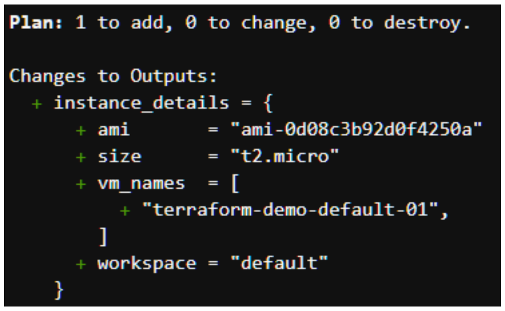
   terraform.tfvars All content currently commented out

   dev.tfvars Variable values that will be used in a new workspace

   prod.tfvars Variable values that will be used in a new workspace

Task 2- Run terraform plan and apply with hardcoded parameter values

1. Ensure you have navigated to the **awslabs\04** folder
2. Run **terraform init**
3. Run **terraform plan**
4. Review the plan output..



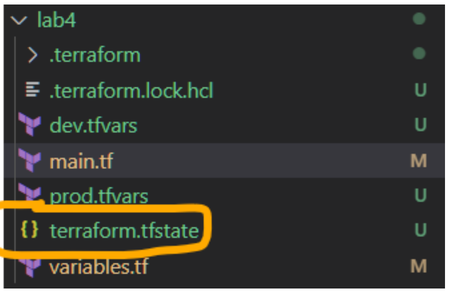
```
Plan: 1 to add, 0 to change, 0 to destroy.

Changes to Outputs:
  + instance_details = {
      + ami       = "ami-0d08c3b92d0f4250a"
      + size      = "t2.micro"
      + vm_names  = [
          + "terraform-demo-default-01",
        ]
      + workspace = "default"
    }
```

5. Run **terraform apply** followed by **yes**
6. Switch to the Console and verify the creation of the EC2 instance in us-west-2..

☐	terraform-demo-default-01	i-04b1501...	Running		t2.micro	us-west-2a

7. Note the creation of a state file in the root folder..

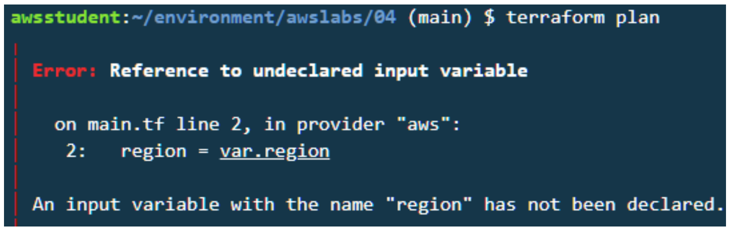


```
lab4
  .terraform
  .terraform.lock.hcl   U
  dev.tfvars            U
  main.tf               M
  prod.tfvars           U
  terraform.tfstate     U
  variables.tf          M
```

8. **Takeaway**: Hardcoded parameter values will always be used if they exist. This can make the code inflexible and static

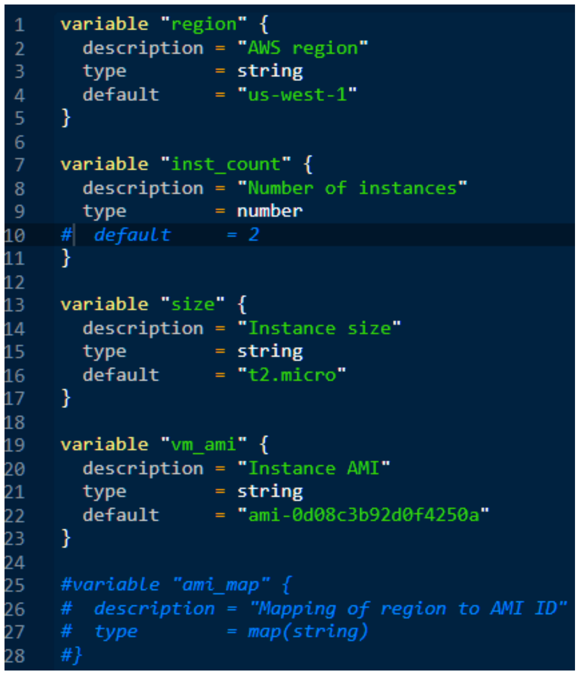
Task 3- Substitute hardcoded parameter vales with variables

1. In **main.tf**; Replace hard-coded region "us-west-2" with **var.region** (no quotes)
2. Replace hard-coded ami "ami-0d08c3b92d0f4250a" with **var.inst_ami**
3. Replace hard-coded instance_type “t2.micro” with **var.inst_size**
4. Replace hard-coded count 1 with **var.inst_count**
5. Save the changes.
6. Run **terraform plan** and review the error…



```
awsstudent:~/environment/awslabs/04 (main) $ terraform plan
│
│ Error: Reference to undeclared input variable
│
│   on main.tf line 2, in provider "aws":
│    2:   region = var.region
│
│ An input variable with the name "region" has not been declared.
```

7. **Takeaway**: If variables are referenced in your code, then they **must** be declared.
8. In **variables.tf**; uncomment lines 1 through 24 **except** line 10 which provides default values for the inst_count variable. Leave lines 25 to 28 commented out…



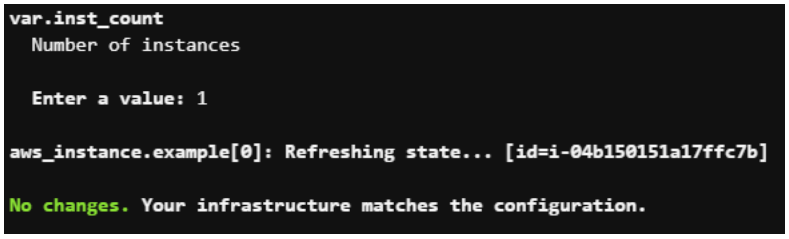
```
1   variable "region" {
2     description = "AWS region"
3     type        = string
4     default     = "us-west-1"
5   }
6
7   variable "inst_count" {
8     description = "Number of instances"
9     type        = number
10  #|  default     = 2
11  }
12
13  variable "size" {
14    description = "Instance size"
15    type        = string
16    default     = "t2.micro"
17  }
18
19  variable "vm_ami" {
20    description = "Instance AMI"
21    type        = string
22    default     = "ami-0d08c3b92d0f4250a"
23  }
24
25  #variable "ami_map" {
26  #  description = "Mapping of region to AMI ID"
27  #  type        = map(string)
28  #}
```

9. Save the changes.

10. Switch to main.tf, uncomment line 18 and save the change

11. Run **terraform plan**

12. When prompted, enter **1** as the number of instances..



```
var.inst_count
  Number of instances

  Enter a value: 1

aws_instance.example[0]: Refreshing state... [id=i-04b150151a17ffc7b]

No changes. Your infrastructure matches the configuration.
```

13. The planning completes using the variable default values if they exist and prompted for when there is no default value. Given that these values are the same as the old static values, the planning phase shows that there are no changes needed

14. In **variables.tf**; uncomment line 10 and save the file

15. Run **terraform plan**

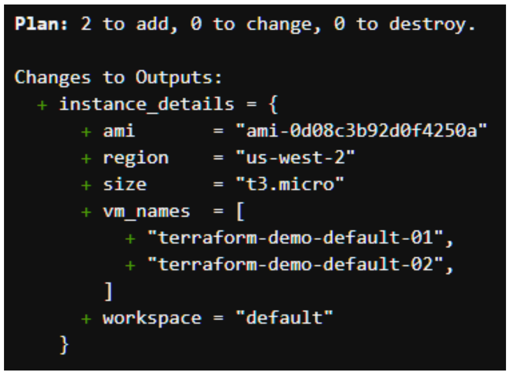
16. The planning completes using all variable values drawn from the variables file. Given that these values are the same as the old static values, the planning phase shows that there are no changes needed.

17. Destroy your deployment using **terraform destroy** followed by **yes**

18. **Takeaway**: If a variable is declared but no value has been assigned then you are prompted for values. If a variable is declared with a default value then this value will be used unless overridden. All changes to variable values will apply to the current deployment as you are working in the default workspace. Workspaces allow multiple deployments to exist simultaneously, all using the same code but with different variable values applied as needed. Workspaces will be introduced later in this lab.

Task 4- Override variable values at the command prompt

1. Enter the following command..
   terraform plan -var="inst_size=t3.micro" -var="inst_count=2"



```
Plan: 2 to add, 0 to change, 0 to destroy.

Changes to Outputs:
  + instance_details = {
      + ami       = "ami-0d08c3b92d0f4250a"
      + region    = "us-west-2"
      + size      = "t3.micro"
      + vm_names  = [
          + "terraform-demo-default-01",
          + "terraform-demo-default-02",
        ]
      + workspace = "default"
    }
```

2. **Takeaway**: Supplying variable values at the command prompt using **-var="   "** has the highest priority and overrides values supplied ***anywhere*** else. In this case **t3.micro** is used as the instance type value and **2** instances would be created. The ami and region values are drawn from the variables file and all resources would be created in the default workspace.

Task 5- Override variable values using terraform.tfvars

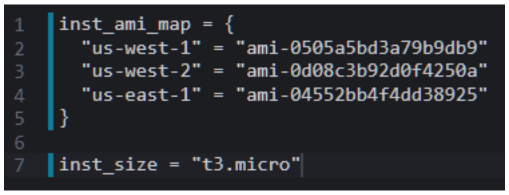
1. Modify line **6** of main.tf from **ami=var.inst_ami** to **ami=var.inst_ami_map[var.region]** and save the changes.

2. This references a new variable **var.inst_ami_map** and removes the use of the variable **var.inst_ami**

3. In **variables.tf**; comment out lines 1 to 5 and uncomment out lines 26 to 29. This removes the **inst_ami** variable and declares the **inst_ami_map** variable.

4. Save the changes.

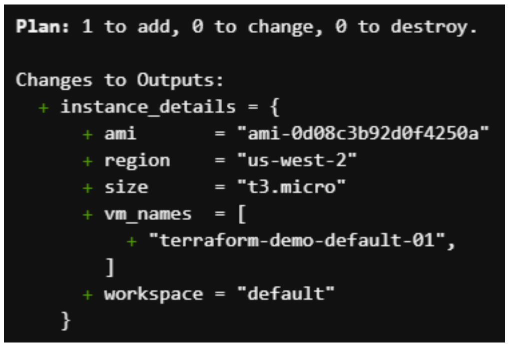
5. Uncomment all the lines in **terraform.tfvars**. This supplies values to the inst_ami_map variable, allowing the ami relevant to the region to be returned. It also sets the size variable value to t3.micro...



```
inst_ami_map = {
  "us-west-1" = "ami-0505a5bd3a79b9db9"
  "us-west-2" = "ami-0d08c3b92d0f4250a"
  "us-east-1" = "ami-04552bb4f4dd38925"
}

inst_size = "t3.micro"
```

6. Run terraform plan



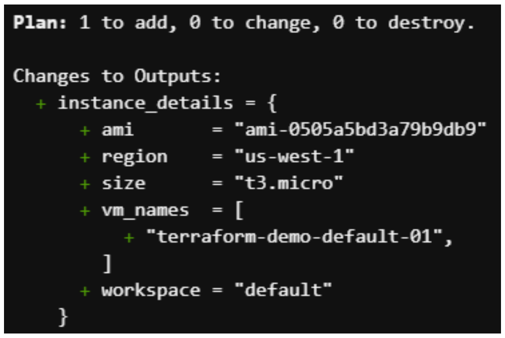
```
Plan: 1 to add, 0 to change, 0 to destroy.

Changes to Outputs:
  + instance_details = {
      + ami       = "ami-0d08c3b92d0f4250a"
      + region    = "us-west-2"
      + size      = "t3.micro"
      + vm_names  = [
          + "terraform-demo-default-01",
        ]
      + workspace = "default"
    }
```

Notice that the size value t3.micro is drawn from terraform.tfvars, overriding the default size in the variables file. When us-west-2 is the region value, the ami ami-0d08c3b92d0f4250a is used.

7. In variables.tf, change the region default to **us-west-1** and save the changes

8. Run terraform plan

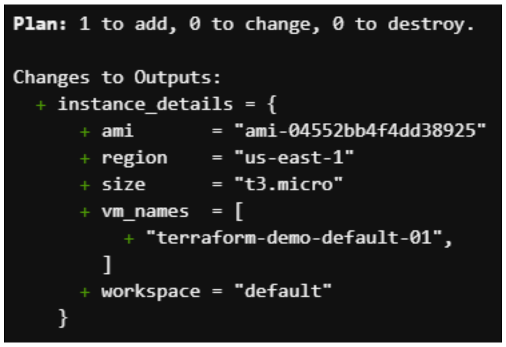


```
Plan: 1 to add, 0 to change, 0 to destroy.

Changes to Outputs:
  + instance_details = {
      + ami       = "ami-0505a5bd3a79b9db9"
      + region    = "us-west-1"
      + size      = "t3.micro"
      + vm_names  = [
          + "terraform-demo-default-01",
        ]
      + workspace = "default"
    }
```

Notice that when us-west-1 is the region, ami-0505a5bd3a79b9db9 is used

9. In variables.tf, change the region default to **us-east-1** and save the changes



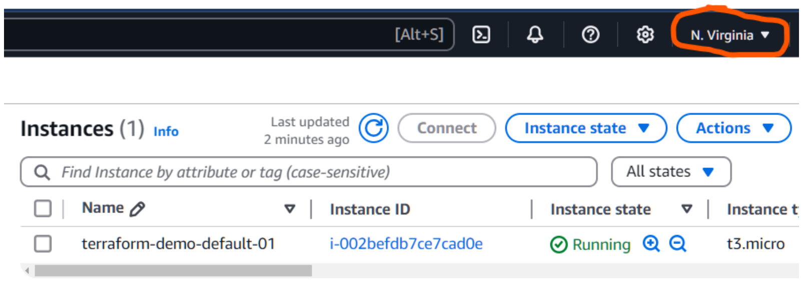
```
Plan: 1 to add, 0 to change, 0 to destroy.

Changes to Outputs:
  + instance_details = {
      + ami       = "ami-04552bb4f4dd38925"
      + region    = "us-east-1"
      + size      = "t3.micro"
      + vm_names  = [
          + "terraform-demo-default-01",
        ]
      + workspace = "default"
    }
```

Notice that when us-east-1 is the region, ami-04552bb4f4dd38925 is used

10. Run **terraform apply** followed by **yes**

11. Switch to the console and verify the creation of the instance in us-east-1 (N. Virginia)…



[Alt+S]

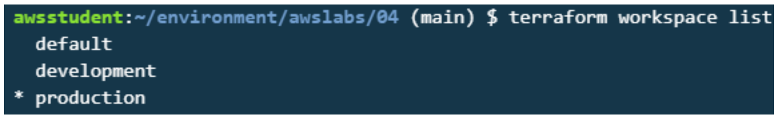
Find Instance by attribute or tag (case-sensitive)
All states

Name	Instance ID	Instance state	Instance t
terraform-demo-default-01	i-002befdb7ce7cad0e	Running	t3.micro

Task 6- Implement Terraform Workspaces

Changing deployment parameters will affect the current deployment. Workspaces allow multiple deployments, using the same base code but with different parameters, to exist simultaneously, each with its own state file. If no new workspaces are created then your deployment is in the **default** workspace which always exists and cannot be deleted.

1. Create two workspaces; “**development**” and “**production**”…
   terraform workspace new development
   terraform workspace new production
   terraform workspace list

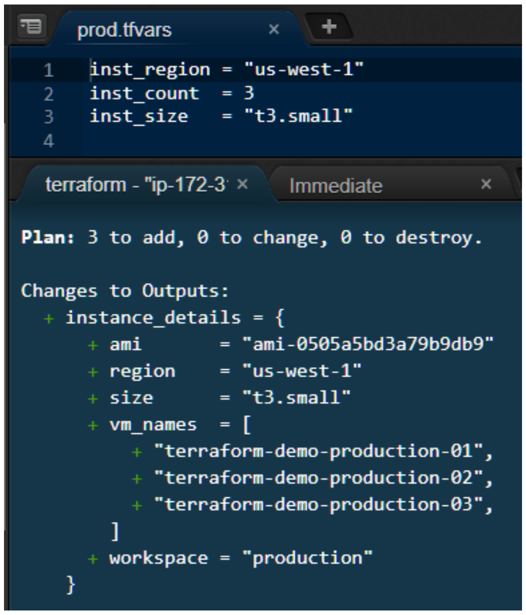


```
awsstudent:~/environment/awslabs/04 (main) $ terraform workspace list
  default
  development
* production
```

2. The * indicates your current workspace is now **production**. The **default** workspace always exists, and this is where your current deployment of an EC2 instance in us-east-1 is tracked by the state file **terraform.tfstate** in the root folder.

3. Note the creation of a new folder "**terraform.tfstate.d**" with an empty subfolder for each of the new workspaces

4. Run **terraform plan --var-file=prod.tfvars**



```
inst_region = "us-west-1"
inst_count  = 3
inst_size   = "t3.small"
```

```
Plan: 3 to add, 0 to change, 0 to destroy.

Changes to Outputs:
  + instance_details = {
      + ami       = "ami-0505a5bd3a79b9db9"
      + region    = "us-west-1"
      + size      = "t3.small"
      + vm_names  = [
          + "terraform-demo-production-01",
          + "terraform-demo-production-02",
          + "terraform-demo-production-03",
        ]
      + workspace = "production"
    }
```

5. tfvar files other than terraform.tfvars are not referenced unless specified at the command line. Here we have specified inclusion of prod.tfvars which contains region value **"us-west-1",** count value **1** and size value **"t3.small"**

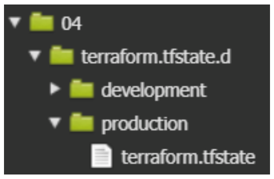
6. If there are conflicts, values from prod.tfvars override default variable values and values in the terraform.tfvars file. The plan shows that the region, size and count value are therefore drawn from the prod.tfvars file. Using us-west-2 as the region, the ami value is drawn from the inst_ami_map variable values defined in the terraform.tfvars file.

7. Notice that the plan will not destroy any resources. Recall that we currently have an EC2 instance deployed in us-east-1. This is in the default workspace and will not be affected as we are now in the production workspace.

8. Run **terraform apply --var-file=prod.tfvars** followed by **yes**

9. Switch to the console and verify the creation of the 3 instances in us-west-1 (N. California). Switch to us-east-1 (N. Virginia) to confirm the instance created in the default workspace still exists

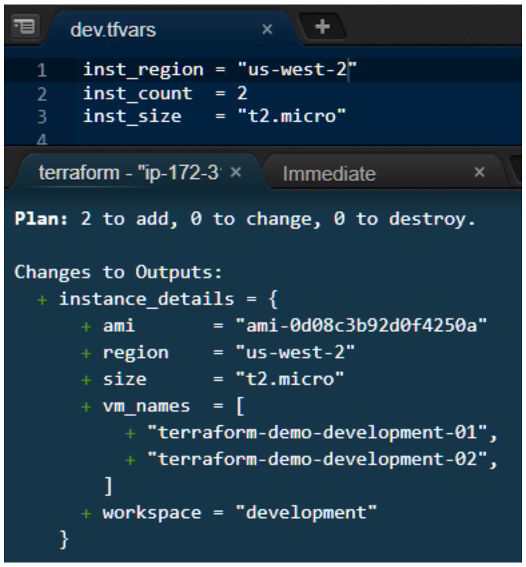
10. In the IDE, expand the terraform.tfstate.d folder and verify the creation of a new state file for the production workspace..



```
▼ 04
  ▼ terraform.tfstate.d
    ▶ development
    ▼ production
        terraform.tfstate
```

11. Move to the development work space; **terraform workspace select development**

12. Run **terraform plan --var-file=dev.tfvars**



```
inst_region = "us-west-2"
inst_count  = 2
inst_size   = "t2.micro"
```

```
Plan: 2 to add, 0 to change, 0 to destroy.

Changes to Outputs:
  + instance_details = {
      + ami       = "ami-0d08c3b92d0f4250a"
      + region    = "us-west-2"
      + size      = "t2.micro"
      + vm_names  = [
          + "terraform-demo-development-01",
          + "terraform-demo-development-02",
        ]
      + workspace = "development"
    }
```

13. If there are conflicts, values from dev.tfvars override default variable values and values in the terraform.tfvars file. The plan shows that the region, size and count value are therefore drawn from the prod.tfvars file. Using us-west-2 as the region, the ami value is drawn from the inst_ami_map variable values defined in the terraform.tfvars file.

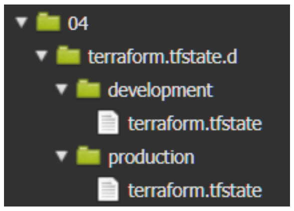
14. Notice that the plan will not destroy any resources. Recall that we now have EC2 instances deployed in us-east-1 and us-west-1. These are in the default and production workspaces respectively and will not be affected as we are now in the development workspace.

15. Run **terraform apply --var-file=dev.tfvars** followed by **yes**

16. Switch to the console and verify the creation of the 2 development instances in us-west-2 (Oregon). Switch to us-east-1 (N. Virginia) to confirm the instance created in the default workspace still exists.

Switch to us-west-1 (N. California) to confirm the 3 production instances created in the default workspace still exists

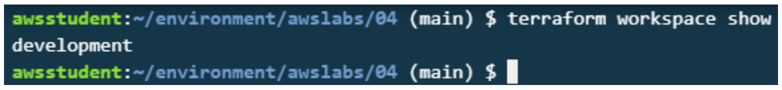
17. In the IDE, expand the terraform.tfstate.d folder and verify the creation of a new state file for the development workspace..



```
▼ 04
  ▼ terraform.tfstate.d
    ▼ development
        terraform.tfstate
    ▼ production
        terraform.tfstate
```

Task 7- Lab Clean-up

1. When deleting resources in workspaces, always pay close attention to workspace you are currently working in. Use **terraform workspace show** to determine your current workspace..



```
awsstudent:~/environment/awslabs/04 (main) $ terraform workspace show
development
awsstudent:~/environment/awslabs/04 (main) $
```

2. Destroy the resources in the current workspace (dev) using..
   terraform destroy --var-file=dev.tfvars

   Note that the tfvars file **must** be specified when performing plan, apply and destroy action.

3. Enter **yes** when prompted

4. Switch to the Console to confirm the deletion of the development instances in us-west-2

5. The current workspace cannot be deleted. Move to the **production** workspace and delete the **development** workspace…

   terraform workspace select production

   terraform workspace delete development

6. Destroy the resources in the current workspace (production) using..
   terraform destroy --var-file=prod.tfvars

7. Enter **yes** when prompted

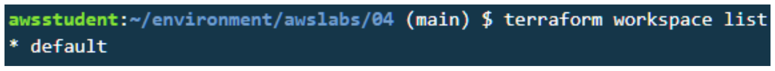
8. Switch to the console to confirm the deletion of the production instances in us-west-1

9. The current workspace cannot be deleted. Move to the **default** workspace and delete the **production** workspace…

   terraform workspace select default

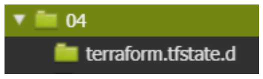
   terraform workspace delete production

10. Verify the deletion of the workspaces, leaving just the default workspace. This cannot be deleted..
    terraform workspace list



```
awsstudent:~/environment/awslabs/04 (main) $ terraform workspace list
* default
```

11. Note that the workspace directories are deleted along with the workspaces themselves…



```
▼ 04
    terraform.tfstate.d
```

12. Destroy the resources in the current workspace (default) using **terraform destroy** followed by **yes**

13. Enter **yes** when prompted

14. Switch to the console to confirm the deletion of the default instance in us-east-1

## Congratulations, you have completed this lab ##
